0008/053

Application No.: 10/664,907Docket No.: 2336-203**REMARKS**

By this Amendment, the specification is amended, the Abstract is amended, and claims 1-3 and 9 are amended. Accordingly, claims 1-5 and 9-13 are pending in this application. These amendments are fully supported throughout the specification and drawings. No new matter is presented in this Amendment. Reconsideration of the application is respectfully requested.

The Office Action objects to the substituted specification submitted with the Amendment filed October 24, 2005, asserting that the term "weight-average molecular weight" is not supported in the specification as originally filed. Similarly, the Office Action rejects claims 1-5 and 9-13 under 35 U.S.C. §112, first paragraph, asserting that the term "weight-average molecular weight" does not appear in the application, as originally filed.

Notwithstanding the assertions of the Office Action, the term "weight-average" in the phrase "weight-average molecular weight" has been replaced with the word "average," as recited in the specification as originally filed. In addition, the Abstract has been similarly amended. Furthermore, the term "weight-average" has been replaced by the word "average" in claims 1-3 and 9.

Therefore, based upon the substitute specification filed with this Amendment, the modifications to the Abstract, and the amendment to the claims, withdrawal of the objection to the specification under 35 U.S.C. §132(a) and the withdrawal of the rejection of claims 1-5 and 9-13 based upon 35 U.S.C. §112, first paragraph, is respectfully requested.

Furthermore, Applicant respectfully asserts that the phrase "average molecular weight," as used in the application, is understood by those knowledgeable in the art of polymers to mean "weight-average" molecular weight as opposed to "number average" molecular weight. Applicant asserts that the "number average" method relies upon the colligative properties of the substance rather than on their nature, and may, in some instances be useful in understanding the chemical reaction of polymers. The "weight-average" method, however, may be more appropriate when considering the properties of polymers, such as in the present application, wherein the polymer used in the ceramic slurry composition is defined by the properties of the polymer and not by the chemical reaction. Accordingly, the phrase "average molecular weight," as used in this application, is intended, and understood by those knowledgeable in the art of polymers, to be interpreted as "weight-average" molecular weight.

Application No.: 10/664,907Docket No.: 2336-203

The Office Action rejects claims 1, 3, 4, and 5 under 35 U.S.C. §102(b) as being anticipated by U.S. Patent No. 4,379,109 to Simpson. Independent claim 1 has been amended to recite a ceramic slurry composition for use in production of a “thin green sheet comprising a thickness of 10  $\mu\text{m}$  or less.” Simpson does not disclose, teach or suggest using specific polymers having an average molecular weight of 400,000 or more, to obtain a green sheet comprising a thickness of 10 microns or less, as recited in amended claim 1. Furthermore, Simpson fails to disclose a slurry composition for use in production of a thin green sheet formed by extruding or stretching, as recited in claim 1. As Simpson fails to disclose all claimed features recited in claim 1, Applicant respectfully submits that claim 1 is patentable over Simpson. Claims 3, 4, and 5 depend from claim 1 and are likewise patentable over Simpson at least for their dependence on an allowable base claim as well as for additional features they recite. Withdrawal of this rejection over Simpson is respectfully requested.

The Office Action alternately rejects claims 1, 3, 4, and 5 under 35 U.S.C. §103(a) as being obvious over Simpson. As presented above, claim 1 has been amended to recite a ceramic slurry composition for use in production of a “thin green sheet comprising a thickness of 10  $\mu\text{m}$  or less.” Applicant further submits that the claimed composition cannot be made using the method of Simpson without undue experimentation because Simpson fails to provide any motivation to use a specific polymer having an average molecular weight of 400,000 or more to produce a thin green sheet comprising a thickness of 10 microns or less by extruding and stretching. Accordingly, claim 1 is patentable over Simpson and withdrawal of this rejection is respectfully requested. Claims 3, 4, and 5 depend from claim 1 and are likewise patentable over Simpson at least for their dependence on an allowable base claim as well as for additional features they recite. Withdrawal of this rejection over Simpson is respectfully requested.

The Office Action further rejects claims 2 and 9 under 35 U.S.C. §103(a) over Simpson. Similar to claim 1, independent claim 2 has been amended to recite a ceramic slurry composition for use in production of a “thin green sheet comprising a thickness of 10  $\mu\text{m}$  or less.” Furthermore, as presented regarding claim 1 above, the composition recited in claim 2 cannot be made using the method of Simpson without undue experimentation because Simpson fails to provide any motivation to use a specific polymer having an average molecular weight of 400,000 or more to produce a thin green sheet comprising a thickness of 10 microns or less by extruding

Application No.: 10/664,907Docket No.: 2336-203

and stretching. Accordingly, it is respectfully submitted that claim 2 is similarly patentable over Simpson. Claim 9 depends from independent claim 2 and is likewise patentable over Simpson at least for its dependence on an allowable base claim as well as for additional features it recites. Withdrawal of this rejection over Simpson is respectfully requested.

The Office Action further rejects claims 10-13 under 35 U.S.C. §103(a) over Simpson in view of Pieterse et al. (U.S. Patent No. 5,268,415). The Office Action asserts that Simpson discloses every feature recited in independent claim 1 and 2, except for teaching other solvents, as recited in claims 10-13. The Office Action asserts that Pieterse remedies this deficiency. Applicant respectfully disagrees.

Claims 1 and 2 disclose a ceramic slurry composition for use in production of a thin green sheet comprising a thickness of 10 µm or less, "by extruding the composition into an extruded sheet." Applicant submits that neither Simpson, nor Pieterse discloses, teaches or suggests extruding the composition as recited in claims 1 and 2. As the combination of Simpson and Pieterse fails to disclose or suggest all the claimed elements of independent claims 1 and 2, claims 1 and 2 are patentable over the combination. Because claims 10-13 depend variously from independent claims 1 and 2, they too are allowable over Simpson and Pieterse. Accordingly, the withdrawal of the rejection of claims 10-13 over the combination of Simpson and Pieterse is respectfully requested.

In view of the foregoing, it is respectfully submitted that this application is in condition for allowance. Favorable reconsideration and prompt allowance of claims 1-5 and 9-13 are earnestly solicited.

Should the Examiner believe that anything further would be desirable in order to place this application in even better condition for allowance, the Examiner is invited to contact the undersigned at the telephone number as set forth below.

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

CERAMIC SLURRY COMPOSITION, METHOD FOR PRODUCING THIN GREEN SHEET BY EXTRUSION, AND ELECTRONIC DEVICE FABRICATED USING THE GREEN SHEET

5 BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to a ceramic slurry composition for producing a thin green sheet using an extrusion-stretching process, and an electronic device fabricated using the green sheet. More particularly, the present invention relates to a ceramic slurry composition for producing a thin green sheet which has a thickness of 10 $\mu$ m or less and can be laminated to form a 40-layer or more stack, a method for producing the green sheet by extrusion, and an electronic device fabricated using the green sheet.

Description of the Related Art

Generally, chip components such as MLCCs (Mutilayer Ceramic Capacitors), chip inductors and the like are fabricated by alternately laminating ceramic green sheets and internal electrodes, and pressing the laminated structure and sintering it.

Ceramic green sheets are commonly produced by a tape

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

casting process. According to the tape casting process, the green sheets are produced by coating a ceramic slurry solution with a uniformly dispersed ceramic powder therein onto a support film using a die coater, doctor blade, etc., and  
5 drying the coated slurry.

To produce a few tens of micrometers or less thick thin green sheet using the tape casting process, the ceramic slurry solution should have a low viscosity. When the viscosity of the slurry solution is, however, too low, the shape  
10 maintenance of a film coated onto the support film becomes difficult, causing an inhomogeneous thickness of a final sheet. In addition, due to a poor strength of the green sheet, damages to the green sheet, such as splitting, are likely to occur when the green sheet is removed from a  
15 substrate. Furthermore, lamination of the thin green sheet is difficult.

In order to prevent the damages to the green sheet, polymers used as binders must have a high molecular weight. However, when the molecular weight of the polymers is too  
20 high, it is difficult to produce a green sheet in the form of a thin film. In addition, since the solubility of the polymers in solvents is low, the polymer particles are precipitated in an inhomogeneously gelled state, which leads to defects in chip components fabricated using the high  
25 molecular weight polymers as binders.

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

PCT publication WO 91/01346 suggests a green sheet which can be produced using an extrusion-stretching process. According to the prior art, a green sheet having a thickness of 25 $\mu$ m or less is produced by extrusion-stretching slurry

5 including a ceramic powder, a polymer having a molecular weight of 400,000 or more, and a solvent for gelling the polymer. Since the extrusion-stretching process does not require any substrate to produce the green sheet, the green sheet has a uniform thickness, compared to green sheets

10 produced using a tape casting process.

In the prior art, since the green sheet is produced using the ultra-high molecular weight polymer, there is a problem of a poor interlayer adhesive strength when laminated and pressed, due to a high modulus of elasticity and a non-  
15 polarity of the polymer. Accordingly, when the green sheet is laminated and sintered, cracks and delamination occur between the laminated green sheets and thus it is difficult to fabricate chip components using the green sheets.

As recent technical development in the field of compact  
20 and high performance electronic devices has progressed, there exists a need for small chip components (electronic devices). To meet this need, thin green sheets are required to have a thickness of 10 $\mu$ m or less and be laminated to form a 40-layer or more stack. However, since the green sheet of the prior  
25 art has a problem that the cracks between layers occur due to

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

its poor interlayer adhesive strength, it cannot be utilized in the fabrication of 40 layers or higher chip components. The lamination of green sheets into 40 layers or higher for fabricating high performance electronic devices causes a  
5 problem of 'pillowing'. This pillowing refers to a phenomenon that when green sheets and internal electrodes are laminated to each other and pressed, a margin zone where no internal electrodes are provided or sufficient internal electrodes are not provided is lower in height than an active zone where  
10 sufficient internal electrodes are provided, and thus the margin zone is collapsed and the active zone is swelled (Fig. 3a). This pillowing phenomenon results in deformation of chip appearance.

15           **SUMMARY OF THE INVENTION**

Therefore, the present invention has been made in view of the above problems of the prior art, and it is an object of the present invention to provide a ceramic slurry composition  
20 for producing a thin green sheet which can be laminated to form a several tens of layer thick stack by increasing interlayer adhesive strength.

It is another object of the present invention to provide a ceramic slurry composition for producing a green sheet which  
25 can solve a pillowing phenomenon that a zone where internal

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

electrodes are formed is swelled, and prevent occurrence of cracks and delamination during sintering.

It is another object of the present invention to provide a method for producing the green sheet using an extrusion-stretching process.

It is yet another object of the present invention to provide an electronic device fabricated using the green sheet. In order to accomplish the above objects of the present invention, there is provided a ceramic slurry composition comprising 20~50wt.% of a ceramic powder, 2~10wt.% of a polymer having an weight-average molecular weight of 400,000 or more, 0.1~2wt.% of a polymer having hydrogen bond-forming functional groups, and 40~75wt.% of a solvent.

In accordance with one aspect of the present invention, there is provided a ceramic slurry composition comprising 20~50wt.% of a ceramic powder, 2~10wt.% of a polymer having an weight-average molecular weight of 400,000 or more, 0.1~2wt.% of a polymer having hydrogen bond-forming functional groups, 40~75wt.% of a solvent, and 1~5wt.% of a polymer having an weight-average molecular weight of 400,000 or less.

In the present invention, the polymer having an weight-average molecular weight of 400,000 or more is referred to as a 'high molecular weight polymer', while the polymer having an weight-average molecular weight of 400,000 or less is referred to as a 'low molecular weight polymer.' One representative

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

example of these polymers is polyolefins.

The hydrogen bond-forming functional groups are selected from the group consisting of -OH, -COOH, -COOCH<sub>3</sub>, -NH<sub>2</sub> and -NHCO. Examples of the polymer having the hydrogen bond-forming functional groups include polyvinylacetates, ethylene-acrylic acid copolymers, ethylene-ethylacryl copolymers, ethylene-methylacryl copolymers, polyacrylic acids, polymethacrylic acids, polylactic acids, polyvinylbutyrals, polyvinylalcohols, polyvinylamines, amine-derived polymers, 10 polyurethanes, polyureas and polyamides.

In accordance with one aspect of the present invention, there is provided a method for producing a thin green sheet comprising extruding a ceramic slurry composition to prepare an extruded sheet, and stretching the extruded sheet, wherein 15 the ceramic slurry composition comprises 20~50wt.% of a ceramic powder, 2~10wt.% of a polymer having an weight-average molecular weight of 400,000 or more, 0.1~2wt.% of a polymer having hydrogen bond-forming functional groups, and 40~75wt.% of a solvent.

20 In accordance with another aspect of the present invention, there is provided a method for producing a thin green sheet comprising extruding a ceramic slurry composition to prepare an extruded sheet, and stretching the extruded sheet, wherein the ceramic slurry composition comprises 25 20~50wt.% of a ceramic powder, 2~10wt.% of a polymer having an

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

weight-average molecular weight of 400,000 or more, 0.1~2wt.% of a polymer having hydrogen bond-forming functional groups, 40~75wt.% of a solvent, and 1~5wt.% of a polymer having an weight-average molecular weight of 400,000 or less.

5       In accordance with yet another aspect of the present invention, there is provided an electronic device comprising dielectric ceramic layers, internal electrodes interposed between the respective dielectric ceramic layers, and external electrodes electrically connected to the respective internal  
10      electrodes, wherein the dielectric ceramic layers are 40-layer or more stacks formed by laminating green sheets, each of which has a thickness of 10 $\mu\text{m}$  or less, the green sheets are produced by extruding the ceramic slurry composition of the present invention to form a sheet and stretching the extruded  
15      sheet, and the internal electrodes contain conductive components.

One example of the conductive components is a nickel (Ni).

20       BRIEF DESCRIPTION OF THE DRAWINGS

The above and other objects, features and other advantages of the present invention will be more clearly understood from the following detailed description taken in  
25      conjunction with the accompanying drawings, in which:

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

Fig. 1 is a cross-sectional view schematically showing the repulsive force occurring during pressing green sheets and internal electrodes;

Fig. 2a is a cross-sectional view schematically showing 5 a stack of green sheets in accordance with an embodiment and an internal electrode, and Fig. 2b is an enlarged view of the circled section of Fig. 2a and shows the influence of a polymer having hydrogen bond-forming functional groups, on the adhesive strength between the green sheets and internal 10 electrodes; and

Fig. 3a is a cross-sectional view schematically showing a conventional electronic device (pillowing phenomenon occurs); while Fig. 3b is a cross-sectional view schematically showing an electronic device fabricated in accordance with the 15 present invention (no pillowing phenomenon occurs).

**DESCRIPTION OF THE PREFERRED EMBODIMENTS**

Hereinafter, the present invention will be explained in 20 more detail.

Since high molecular weight polymers such as polyolefins have a high non-polarity, the adhesive strength between polyolefins and other materials such as metals or ceramics, and between polyolefins themselves is very low. When green 25 sheets containing polyolefin are laminated and sintered,

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

cracks and delamination are likely to happen between layers due to their low adhesive strength. The present inventors have intensively researched to increase the adhesive strength between layers. As a result, it has been found that when a 5 polymer having hydrogen bond-forming functional groups is mixed, the adhesive strength between green sheets is increased, and the draw ratio of an extruded sheet during stretching the extruded sheet is maximized.

A green sheet can be produced from a polymer having an 10 weight-average molecular weight of 400,000 or higher using an extrusion-stretching process. However, the green sheet thus produced has a high Young's module of several ten to hundred GPa. This high Young's module enables the formation of a support-free or self-supporting film and lamination of the 15 film. However, when the green sheets and internal electrodes are laminated and pressed to each other, a repulsive force acts on the electrode layer and thus makes the depression of the electrode layer into the green sheets difficult. In addition, the repulsive force reduces the adhesive strength 20 between the layers (see, Fig. 1). Furthermore, the repulsive force does not permit fabrication of a uniformly thick film. The present inventors have made efforts to solve the above-mentioned problems and, as a result, it has been found that 25 the combination of an ultrahigh molecular weight polymer and a relatively low molecular weight polymer can reduce the

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

repulsive force between an electrode layer and green sheets due to a high modulus of elasticity of the ultrahigh molecular weight polymer and facilitate the lamination of the layers, thereby easily fabricating an electronic device.

5

Hereinafter, the ceramic slurry composition of the present invention is explained.

## [Ceramic Powder]

10       The ceramic powder used in the present invention includes dielectric ceramic powders, ferrite ceramic powders, magnetic ceramic powders, piezoelectric ceramic powders, insulating ceramic powders, etc. As dielectric ceramic powders, barium titanate, strontium titanate and lead titanate  
15      can be used. As insulating ceramic powders, silica can be used. The ceramic powder is used in the form of a fine powder to obtain its optimum smooth surface. Preferably, the ceramic powder has a particle size of 0.01~1 $\mu$ m. The content of the ceramic powder is preferably in the range of 20~50wt.%, based  
20      on the total weight of the ceramic slurry composition. When the content of the ceramic powder is less than 20wt.%, the packing density of a final product becomes low and pores are likely to be formed, which causes defects of the final product. When the content of the ceramic powder exceeds  
25      50wt.%, relative content of the polymer is small.

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

Accordingly, the strength of the green sheet is poor and thus the forming of the green sheet is difficult.

**[Polymer]**

5       A representative example of the polymer is polyolefins. Examples of the polyolefins include polyethylenes, polypropylenes, polystyrenes, polyisobutylenes, etc. As a polymer, a polymer having an weight-average molecular weight of 400,000 or more (simply, referred to as a 'high molecular weight polymer') can be used alone, or in combination with a 10 polymer having an weight-average molecular weight of 400,000 or less (simply, referred to as a 'low molecular weight polymer'). The combination of the high molecular weight polymer and the low molecular weight polymer reduces the 15 repulsive force between an electrode layer and green sheets caused by a high modulus of elasticity of the high molecular weight polymer and facilitate the lamination of the layers, thereby easily fabricating an electronic device.

The content of the high molecular weight polymer is 20 preferably within the range of 2~10wt.%, based on the total weight of the ceramic slurry composition. When the content is less than 2wt.%, forming into a sheet is difficult. When the content exceeds 10wt.%, the forming into a sheet is difficult and ceramic packing density is reduced when sintered.

25       When the low molecular weight polymer is combined with

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

the high molecular weight polymer, it is preferable that the content of the low molecular weight polymer is within the range of 1-5 wt.%. When the content is less than 1wt.%, there are risks that interlayer cracks and a pillowing phenomenon occur due to the repulsive force of the high molecular weight polymer when laminated into high layers. When the content of the low molecular weight polymer exceeds 5wt.%, the strength of the green sheet is lowered.

10 [Polymer having hydrogen bond-forming functional group]

Referring to Figs. 2a and 2b, the polymer having hydrogen bond-forming functional groups improves the adhesive strength between green sheets. In addition, the polymer maximizes the draw ratio during stretching an extruded sheet.

15 The hydrogen bond-forming functional groups are selected from the group consisting of -OH, -COOH, -COOCH<sub>3</sub>, -NH<sub>2</sub>, -NHCO and the like. Examples of the polymer having the functional groups include polyvinylacetates, ethylene-acrylic acid copolymers, ethylene-ethylacryl copolymers, ethylene-methylacryl copolymers, polyacrylic acids, polymethacrylic acids, polyvinylbutyrals, polyvinylalcohols, polyvinylamines, amine-derived polymers, polyurethanes, polyureas, polyamides and the like.

20 The content of the polymer having hydrogen bond-forming functional groups is preferably in the range of 0.1~2wt.%.

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

based on the total weight of the ceramic slurry composition. When the content is less than 0.1wt.%, cracks between the green sheet layers are likely to occur due to fewer hydrogen bonds. When the content exceeds 2wt.%, the sheets are 5 difficult to handle on account of their increased tackiness.

[Solvent for gelling high molecular weight polymer]

A high molecular weight polymer has little or no flowability in its molten state. Accordingly, the polymer is 10 mixed with a solvent at high temperature to form a gel. This formation of gel increases the melt flowability of the polymer. Thereafter, the gel is subjected to an extrusion, and then evaporated and extracted to remove the solvent.

In the present invention, as the solvent for gelling 15 the high molecular weight polymer, paraffins, decahydronaphthalene, tetrahydronaphthalene, naphtha, mineral spirit, toluene, xylene, hexane, chloroform or a mixture thereof, can be used.

The content of the solvent is preferably within the 20 range of 40~75wt.%, based on the total weight of the ceramic slurry composition. When the content of the solvent is less than 40wt.%, there is a need to increase the extrusion temperature. When the extrusion temperature is too high, the polymer tends to be decomposed, making sheet forming 25 difficult. When the content of the solvent exceeds 75wt.%,

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

uniform shape of an extruded sheet cannot be retained, also making the sheet forming difficult.

**[Other additives]**

5       The ceramic slurry composition of the present invention may further comprise a dispersant, a wetting agent, etc., as an additive. The additive preferably has a content of 0.01~1wt.%, based on the total weight of the ceramic slurry composition.

10      A method for producing the green sheet of the present invention and an electronic device fabricated using the green sheet will now be explained.

The green sheet is produced by extruding the ceramic slurry composition of the present invention, followed by 15 stretching. The method will be explained in terms of the respective steps.

**[Preparation of slurry]**

First, a ceramic dispersion is prepared.

20      A ceramic powder is dispersed in a mixture of a solvent and a suitable dispersant. Examples of the solvent include aromatic hydrocarbons such as decalin or paraffin oils or aliphatic hydrocarbons. To disperse the ceramic powder, a bead mill, a ball mill or an attritor, a paint shaker, a sand 25 mill, etc., can be used. During dispersing the ceramic

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

- powder, too high grinding power leads to excessive damage to the ceramic powder. That is, too high grinding power results in deteriorated crystallinity of the ceramic powder and increased specific surface area, thereby failing to obtain 5 intended electrical properties. To prevent such problems, a high-pressure dispersion process can be performed. The process is carried out by dispersing the ceramic powder using a collisional energy, and rapidly passing through a tapered channel under high pressure.
- 10 Next, ceramic slurry is prepared.
- The ceramic slurry is prepared by mixing the ceramic dispersion, the high molecular weight polymer (if necessary low molecular weight polymer), the polymer having hydrogen bond-forming functional groups and the solvent. If necessary, 15 an additive is further added to the mixture.

**[Production of green sheet]**

The ceramic slurry thus prepared is extruded to be shaped into a green sheet. First, the ceramic slurry 20 composition of the present invention is fed into an extruder and gelled therein. The gelled mixture is extruded to be shaped into a sheet form, rapidly cooled to obtain a gel crystal, and dried.

The temperature of the extruder is preferably within the 25 range of 150~200°C, and that of a die (T-die or coat hanger-

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

die) in the extruder is preferably set to a temperature of 160~180°C.

The dried sheet is then stretched. The dried sheet may be stretched either biaxially or uniaxially. In the case of 5 the biaxial stretching, the dried sheet is stretched in longitudinal and transverse direction at the same draw ratio, or at a draw ratio higher in longitudinal direction than in transverse direction, or vice versa. The longitudinal and transverse stretching may be alternatively carried out, but 10 preferably carried out simultaneously. The biaxial stretching is preferably carried out at 70~200°C.

Extraction is carried out to remove remaining solvents, followed by drying to produce a green sheet. The green sheet thus produced has a thickness of a few µm and contains 15 micropores therein.

**[Fabrication of electronic device]**

After an electrode layer is formed using the green sheets thus produced, the green sheets are laminated in a 20 desired number of layers using a heat-pressing process. After lamination, a binder burn out and a sintering process are carried out to fabricate an electronic device.

Since the green sheet produced using an extrusion-stretching process contains a number of pores therein, it has 25 a low density. The combination of the low-density green sheet

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

and a low molecular weight polymer helps prevent a pillowing phenomenon.

Hereinafter, the present invention will be described in more detail with reference to the following Examples.

5

[Example 1]

Hypermer KD-3 (ICI) as a dispersant and OLOA1200 (Chevron ornite) as a wetting agent were dissolved in decahydronaphthalene as a solvent 1 (first use of solvent 1).

10 To the resulting solution, barium titanate having a diameter of 0.4 $\mu$ m was added. After the mixture was dispersed using a basket mill for 3 hours, decahydronaphthalene (second use) or a paraffin oil as a solvent 2 were added to the dispersion, and then polymers were added thereto with slow  
15 stirring. The resulting mixture was stirred for 1 hour to obtain a slurry solution. The mixing ratio in the slurry solution is shown in Table 1 below.

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

The slurry solution was fed into a twin-screw extruder  
 5 equipped with a melt pump and a coat hanger die while gently  
 stirring, and gelled to produce an extruded sheet. At this  
 time, the temperature of the extruder and the die were set to  
 100~220°C and 170°C, respectively. After the extruded sheet  
 was passed through a cold water bath to obtain a gel crystal  
 10 and partially dried, the dried sheet was biaxially stretched  
 at a draw ratio of of 10 x 10 at 110°C. The stretched sheet

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

was passed through a hexane solution to remove solvents remaining therein, and finally produce a green sheet having a thickness of 10 $\mu$ m.

The produced green sheet was cut to prepare single layer  
5 green sheets. The single layer green sheets were pressed to each other under 5 MPa at 130°C for 3 minutes and laminated in a 20-layer stack to prepare a cover sheet. After the cover sheet was fixed, one single layer green sheet was pressed under 8 MPa at 130°C for 5 seconds. An electrode layer was  
10 formed using a screen printing process, and dried at 70°C for 5 minutes. After the procedure was repeated 40 times to form a 40-layer active layer, the cover sheet was pressed thereto, and subjected to a dicing and trimming process. Finally, the binder was burned out in nitrogen atmosphere and sintering was  
15 carried out in a weak reducing atmosphere to fabricate an electronic device.

The adhesive strength between sheets of the electronic device thus fabricated was measured. The results are shown in Table 2 below. The pillowowing phenomenon was visually  
20 observed.

Table 2

Examples	Adhesive strength between sheets (kgf/cm)

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

Example 1	21
Comparative Example 1	7
Example 2	18
Example 3	14

As shown in Table 2, the electronic device (Example 3) fabricated by mixing the ceramic slurry with the polymer having hydrogen bond-forming functional groups showed an adhesive strength 2 times higher than that of the electronic device (Comparative Example 1) containing no polymer having hydrogen bond-forming functional groups. In addition, the adhesive strength between sheets of the electronic devices (Examples 1 and 2) fabricated by mixing the low molecular weight polymer was greatly improved.

As shown in Fig. 3(a), a pillowing phenomenon wherein a margin zone is collapsed and an active zone is swelled was visually observed in the electronic device of Comparative Example 1. By contrast, no pillowing phenomenon was visually observed in the electronic devices of Examples 1~3.

As apparent from the above description, since the green sheet of the present invention is produced using an extrusion-stretching process, no substrate (support film) is required, unlike a tape casting process. In addition, since the ceramic slurry composition of the present invention is gelled prior to removal of solvents, forming into a low-density green sheet is

**SUBSTITUTE SPECIFICATION SHOWING CHANGES**

possible. Accordingly, the green sheet can be depressed to prevent occurrence of a pillowing phenomenon. Furthermore, the combination of a polymer having hydrogen bond-forming functional groups increases the adhesive strength between 5 layers, and the combination of a high molecular weight polymer and a low molecular weight polymer can reduce the repulsive force between electrode layers and improve formability of the green sheet. The low molecular weight polymer and the polymer having hydrogen bond-forming functional groups act as a binder 10 to improve stretchability of the high molecular weight polymer.

Although the preferred embodiments of the present invention have been disclosed for illustrative purposes, those skilled in the art will appreciate that various modifications, 15 additions and substitutions are possible, without departing from the scope and spirit of the invention as disclosed in the accompanying claims.
